IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

Box PATENT APPLICATION  
TO THE COMMISSIONER FOR PATENTS  
Washington, D.C. 20231

24197

Transmitted herewith for filing is the patent application of:

Inventor: Noriyuki Hirayanagi

For: ALIGNMENT-MARK DETECTION METHODS AND  
DEVICES FOR CHARGED-PARTICLE-BEAM  
MICROLITHOGRAPHY, AND MICROELECTRONIC-DEVICE  
MANUFACTURING METHODS COMPRISING SAME

jc918 U.S. PTO  
09/09/659211  
09/11/00

Enclosed are:

- 10 pages of specification, 4 pages of claims, an abstract and a Combined Declaration and Power of Attorney.
- 5 sheets of informal drawings.
- An assignment of the invention to Nikon Corporation and a Recordation Cover Sheet.
- A certified copy of Japanese patent application no. 11-257003.

FILING FEE					
For	Claims	Number	Number	Basic Fee	
	Filed	Free	Extra	Rate	\$690.00
Total Claims	12	20	= 0	\$18.00	\$ 0.00
Independent Claims	2	3	= 0	\$78.00	\$0.00
Multiple Dependent Claim Fee				\$260.00	\$0.00
<b>TOTAL FILING FEE</b>					<b>\$690.00</b>

- A check in the amount of \$730.00 to cover the filing fee and the assignment recordal fee is enclosed.

PATENT  
Attorney Reference Number 4641-55447

- The Director is hereby authorized to charge any additional fees which may be required in connection with the filing of this application and recording any assignment filed herewith, or credit over-payment, to Account No. 02-4550. A copy of this sheet is enclosed.
- Please return the enclosed postcard to confirm that the items listed above have been received.

Respectfully submitted,

KLARQUIST SPARKMAN CAMPBELL  
LEIGH & WHINSTON, LLP

**ALIGNMENT-MARK DETECTION METHODS AND DEVICES**  
**FOR CHARGED-PARTICLE-BEAM MICROLITHOGRAPHY,**  
**AND MICROELECTRONIC-DEVICE MANUFACTURING**  
**METHODS COMPRISING SAME**

5

**Field of the Invention**

This invention pertains to microlithography (projection-transfer of a pattern, defined on a reticle, to a suitable substrate). Microlithography is a key technology used in the manufacture of microelectronic devices such as integrated circuits, 10 displays, and the like. More specifically, this invention pertains to aligning the reticle and substrate for accurate pattern transfer.

**Background of the Invention**

In charged-particle-beam (CPB) microlithography (i.e., microlithography 15 performed using a charged particle beam such as an electron beam or ion beam), as in optical microlithography (i.e., microlithography performed using visible or ultraviolet light), obtaining accurate alignment between the reticle and the substrate is extremely important. Current microlithography apparatus include sophisticated devices for determining reticle-substrate alignment. In a CPB microlithography 20 apparatus as currently available, these alignments involve impinging a charged particle beam on a mark on the substrate or substrate stage and detecting charged particles (e.g., electrons) backscattered from the mark.

A conventional method and apparatus for detecting an alignment mark in CPB microlithography are shown in FIGS. 3(A)-3(C). FIG. 3(A) shows certain 25 aspects of such an apparatus employing an electron beam EB; FIG. 3(B) depicts certain details of scanning an alignment mark on the substrate (wafer) using the electron beam EB; and FIG. 3(C) shows a typical backscattered-electron (BSE) signal waveform obtained by scanning the alignment mark in FIG. 3(B).

The apparatus of FIG. 3(A) includes an electron-beam source (electron gun) 1 30 that produces an electron beam EB propagating downstream of the electron gun 1. The electron beam EB passes through an electron-optical system OS and irradiates a

silicon wafer or other suitable specimen 7. The wafer 7 is mounted on a wafer stage 5. The wafer stage 5 is movable to allow exposure of the entire wafer 7 and to allow loading and unloading of the wafer 7 for exposure.

The electron beam EB propagating toward the wafer 7 is deflected by a scanning deflector 3 located downstream of the electron-optical system OS. The scanning deflector 3 is connected to a deflector controller 4. The scanning deflector 3 is controlled by the controller 4, which thus causes the electron beam EB to be scanned over the wafer 7 in two dimensions.

Whenever the electron beam EB irradiates the wafer 7 in this manner, backscattered electrons are generated and propagate in an upstream direction from the upstream-facing surface of the wafer 7. The backscattered electrons are detected by a BSE detector 9. As the BSE detector 9 receives backscattered electrons, it produces a corresponding electrical "BSE signal" that is routed to a controller 10 via an interface 8. The interface 8 comprises an amplifier and an analog-to-digital (A/D) converter that convert the BSE signal from the BSE detector 9 into input data usable by the controller 10. The controller 10 comprises an arithmetic processor that calculates a position of the alignment mark 7a based on the input data. Thus, as the electron beam EB is scanned across the mark 7a on the wafer 7, changes in the BSE signal are monitored.

Before the electron beam EB is incident on the wafer 7, the transverse profile of the beam is shaped by passage of the beam through a beam-shaping aperture (not shown) situated within the electron-optical system OS. Passage of the beam through the beam-shaping aperture trims the periphery of the beam to a desired size and shape before the beam is scanned over the alignment mark 7a. An exemplary alignment mark 7a is shown in FIG. 3(B), in which elements of the alignment mark 7a are defined by corresponding channels 7b etched into the surface of the wafer 7. Ideally, whenever the electron beam EB scans the alignment mark 7a, the resulting BSE signal exhibits a distinctive waveform that corresponds to the elevational profile of the alignment mark 7a, as shown in FIG. 3(C). Due to the distinctiveness of the waveform formed by passing the beam over the mark 7a, it is possible to

detect the position of the alignment mark 7a from the obtained BSE signal waveform.

As an alternative to defining elements of the alignment mark 7a by etched channels in the wafer surface, the elements of the alignment mark can be defined by

5 forming corresponding regions of a patterned layer of a heavy metal (e.g., Ta or W) on the wafer surface. Regions of the layer of heavy metal exhibit a high level of electron backscattering relative to the wafer material.

In the apparatus of FIG. 3(A), whenever the specimen 7 is a silicon wafer having well-defined crystal properties, the BSE signal waveform that is obtained

10 includes components derived from the alignment mark 7a and from the crystal properties of the specimen 7 itself. These signals are detected simultaneously, and thus both contribute substantially to the BSE signal waveform.

For example, if the electron beam incident on a crystalline silicon wafer 7 has an energy of approximately 100 keV, then changes in signal amplitude originating

15 from the crystalline properties of the wafer material will be nearly equal to changes in the amplitude of the BSE signal from an alignment mark formed by channels in the wafer surface. The resulting lack of differentiation in the BSE signal produced by the alignment mark versus by the wafer surface causes a significant reduction in the accuracy with which the position of the alignment mark can be detected.

20

### Summary of the Invention

In view of the shortcomings of the prior art as summarized above, an object of the invention is to provide methods and apparatus that achieve more accurate detection of alignment-mark positions for charged-particle-beam (CPB)

25 microlithography.

To such end, and according to a first aspect of the invention, methods are provided for detecting, in the context of charged-particle-beam (CPB) microlithography of a specimen, a position of an alignment mark on the specimen. In a representative embodiment of such a method, a charged particle beam (e.g.,

30 electron beam or ion beam) is irradiated onto an area of the specimen lacking an alignment mark. Backscattered charged particles propagating from the irradiated

area are detected so as to obtain a first backscattered-particle signal. The first backscattered-particle signal can serve as a “background” signal. The charged particle beam also is irradiated onto the alignment mark. Backscattered charged particles propagating from the irradiated alignment mark are detected so as to obtain 5 a second backscattered-particle signal. The first backscattered-particle signal is subtracted from the second backscattered-particle signal to obtain a difference signal. The alignment-mark position is determined from the difference signal.

In this method, the background signal can be obtained by scanning the charged particle beam across a smooth planar region of a surface of the specimen. In 10 a specimen made of a material (e.g., monocrystalline silicon) having a crystal-orientation plane, the first backscattered-particle signal can be obtained by scanning the charged particle beam across a smooth planar region of a surface of the specimen representing a crystal-orientation plane of the specimen. The subtraction of the first backscattered-particle signal from the second backscattered-particle signal removes 15 data, concerning the crystal-orientation of the specimen, from the difference signal that otherwise would obfuscate data in the difference signal pertaining to the alignment mark. I.e., the difference signal in such an instance contains data regarding the configuration and other aspects of the alignment mark but not data concerning the crystal orientation of the specimen.

20 If the specimen is monocrystalline, then a background signal will be the same from any smooth planar region of the specimen surface, and hence can be obtained conveniently from any such smooth planar region of the specimen surface. Data in the background signal can be stored for later recall when it is desired to remove the “noise” represented in the background signal from an alignment-mark detection 25 signal. In addition, the amplitude of a backscattered-particle signal from a monocrystalline surface varies with changes in the angle of incidence of the beam on the surface. Subtracting the background signal removes this effect from the difference signal.

According to another aspect of the invention, devices are provided for 30 measuring an alignment of the substrate (in the context of a CPB microlithography apparatus including a CPB source that produces a charged particle beam, a CPB-

optical system through which the charged particle beam passes from the CPB source to a substrate, and a substrate stage on which the substrate is placed for exposure by the charged particle beam). A representative embodiment of the device includes a deflector situated and configured to deflect the charged particle beam to cause the

5 beam to irradiate a predetermined location on the substrate mounted on the substrate stage, so as to cause the location to produce backscattered particles. The device also includes a backscattered-particle detector situated and configured to detect backscattered charged particles produced by the location on the substrate as the location is irradiated by the charged particle beam. The device also includes a

10 controller connected to the deflector and the backscattered-particle detector. The controller is configured to: (1) energize the deflector in a manner causing the deflector to irradiate the beam on a first location on the substrate lacking an alignment mark, thereby producing a background backscattered-particle signal; (2) energize the deflector in a manner causing the deflector to irradiate the beam on a

15 second location on the substrate in which an alignment mark is formed, thereby producing an alignment-mark backscattered-particle signal; (3) calculate a difference signal by subtracting the background signal from the alignment-mark signal; and (4) determine the position of the alignment mark from the difference signal.

The present invention can be applied to any type of CPB microlithography, including (but not limited to) CPB direct writing, block exposure, and divided-reticle exposure (involving exposure of individual subfields and stitching of individual subfield images).

The foregoing and additional features and advantages of the invention will be more readily apparent from the following detailed description, which proceeds with reference to the accompanying drawings.

#### Brief Description of the Drawings

FIGS. 1(A)-1(C) are plots of exemplary backscattered-particle signal waveforms obtained in an alignment-mark-position detection method according to a

30 representative embodiment of the invention. FIG. 1(A) is a backscattered-electron (BSE) signal waveform obtained when scanning an electron beam over an alignment

mark formed on a silicon substrate. FIG. (1B) is a BSE signal waveform obtained when an electron beam is scanned over a smoothly planar region (lacking an alignment mark) of the silicon substrate. FIG. 1(C) is a BSE signal waveform obtained by subtracting the waveform of FIG. 1(B) from the waveform of FIG. 1(A).

5 FIGS. 2(A)-2(B) depict exemplary effects, on a backscattered-particle (e.g., BSE) signal, caused by crystalline properties of a monocrystalline silicon substrate. FIG. 2(A) depicts a representative electron channeling pattern of "Kikuchi bands" obtained by multiple scans of a 111 silicon substrate in two dimensions using an electron beam. FIG. 2(B) is an exemplary signal waveform obtained by scanning  
10 between points B-B of FIG. 2(A).

FIG. 3(A) is an oblique schematic depiction of certain details of a conventional device, on a charged-particle-beam (CPB) microlithography apparatus, for scanning the charged particle beam over an alignment mark on a substrate.

15 FIG. 3(B) is a schematic elevational view of an alignment mark being scanned by a charged particle beam.

FIG. 3(C) is a representative BSE signal waveform obtained from the scan shown in FIG. 3(B).

FIG. 4 is a process flowchart for manufacturing a microelectronic device, wherein the process includes a microlithography method according to the invention.

20 FIG. 5 is a process flowchart of certain aspects of a microlithography method as used in the process of FIG. 4.

### Detailed Description

The following discussion is in the context of an electron-beam  
25 microlithography apparatus. However, it will be understood that the principles described below can be applied with equal facility to use of other types of charged particle beams, such as an ion beam.

FIGS. 1(A)-1(C) depict exemplary respective backscattered-electron (BSE) signal waveforms obtained using a representative embodiment of an alignment-mark  
30 detection method according to the invention. FIG. 1(A) shows a BSE signal waveform obtained by scanning the electron beam over an alignment mark formed

on a silicon wafer. FIG. 1(B) shows a BSE signal waveform obtained by scanning the electron beam over a smooth surface of silicon that lacks an alignment mark. The signal waveform shown in FIG. 1(B) includes the effects of electron-beam channeling discussed below with respect to FIG. 2(B). FIG. 1(C) is obtained by

5 subtracting the plot of FIG. 1(B) from the plot of FIG. 1(A).

The specimen used to produce the signal waveforms of FIGS. 1(A)-1(C) is a monocrystalline silicon wafer of which the upstream-facing surface has a lattice orientation of 111. An electron beam, incident on such a specimen, is scanned across the surface in a manner as shown in FIG. 3(A), in which the angle of incidence of the  
10 electron beam on the specimen exhibits a slight change with the amount of lateral deflection imparted to the beam by the deflector 3. As the electron beam is scanned across the surface, the BSE detector 9 produces a BSE signal that can be used to produce an “electron channeling pattern” (ECP). A representative ECP for 111 silicon is shown in FIG. 2(A). The BSE signal amplitude for a scan along the line  
15 B-B is shown in FIG. 2(B).

More specifically, FIG. 2(A) shows an exemplary profile or map of “Kikuchi bands” 12 produced by scanning a 111 surface of silicon with an electron beam. The scanning is performed over coordinates in the X- and Y-directions. Along each thick line 12 in FIG. 2(A), the BSE signal is reduced, compared to other regions, as a  
20 result of interactions of the incident electrons with atoms of the crystalline surface. In FIG. 2(A), the abscissa (horizontal axis) is the X-direction deflection output (to the beam) and the ordinate (vertical axis) is the Y-direction deflection output to the beam. Thus, FIG. 2(A) indicates a map of results of respective summed deflections of the beam in the X-direction and in the Y-direction. A representative BSE signal  
25 detected by a BSE detector, of an electron beam scanned along the line B-B of FIG. 2(A), is shown in FIG. 2(B). Hence, as shown in FIG. 2(A), the BSE signal is weaker at certain direct relationships between the X-direction deflection output and the Y-direction deflection output. The Kikuchi lines 12 connecting these points are arranged in a characteristic pattern for 111 silicon.

30 FIG. 2(B) is an example BSE signal waveform obtained by scanning the beam in one dimension between the points B-B of FIG. 2(A). FIG. 2(B) shows the

characteristic drop of BSE signal amplitude as the scanned beam crosses the Kikuchi lines 12. As noted above, the waveform of FIG. 2(B) exhibits a characteristic change in amplitude corresponding to certain angles of incidence of the electron beam in the X-Y plane. The particular BSE signal waveform shown in FIG. 2(B) reflects

5 characteristics of the crystal lattice of the specimen being scanned. Patterns that are similar are obtained from specimens having identical crystal orientations.

The BSE signal waveform originating from the crystal properties of the specimen can be removed from the signal. For example, a BSE signal waveform such as that of FIG. 1(B) is obtained and stored in a memory. The FIG.-1(B)

10 waveform reflects the crystalline properties of the specimen as manifest on a smooth plane thereof on which the monocrystalline silicon has identical crystalline properties. The FIG.-1(B) waveform is subtracted from the BSE signal waveform of FIG. 1(A) obtained from the alignment mark. The resulting signal, shown in FIG. 1(C), is representative of a signal having a waveform arising only from  
15 characteristics of the alignment mark, without obfuscating influences of the material on which the alignment mark is located. Furthermore, when obtaining the waveforms of FIGS. 1(A) and 1(B), the scanning conditions of the electron beam and the inclination of the specimen relative to the electron beam must be the same.

Whenever a resist is coated onto a surface of a silicon substrate, the  
20 amplitude of the BSE signal waveform originating from the crystalline properties of the specimen decreases but does not decrease entirely to zero. Therefore, methods according to the invention as described above are effective for improving the detection accuracy of the alignment mark position.

Methods for detecting alignment-mark positions, as described above, can be  
25 executed automatically via commands from the controller 10 of the apparatus shown in FIG. 3(A).

FIG. 4 is a flowchart of an exemplary semiconductor-device fabrication method to which apparatus and methods, according to the invention, for performing a microlithographic exposure including detection of alignment-mark positions  
30 readily can be applied. The fabrication method generally comprises the main steps of wafer production (wafer fabrication), reticle production (reticle preparation) for

use in microlithography of the wafer, wafer processing, device assembly (including chip dicing and making each chip functional), and chip inspection. Each step usually comprises several sub-steps.

Among the main steps, wafer processing is key to achieving the smallest  
5 feature sizes (critical dimensions) and best inter-layer registration. In the wafer-  
processing step, multiple circuit patterns (such as for memories and/or CPUs) are  
layered successively atop one another on the wafer, wherein the formation of each  
layer typically involves multiple sub-steps. Usually, many operative semiconductor  
devices are produced on each wafer.

10 Typical wafer-processing steps include: (1) thin-film formation (by, e.g.,  
CVD or sputtering) to form a dielectric layer for electrical insulation or a metal layer  
for connecting wires or forming electrodes; (2) oxidation the thin film or substrate  
surface; (3) microlithography to form a resist pattern for selective processing of the  
thin film or the substrate itself; (4) etching or analogous step (e.g., anisotropic dry  
15 etching) to etch the thin film or substrate according to the resist pattern; (5) doping  
or other implantation step as required to implant ions or other impurities into the thin  
film or wafer; (6) resist stripping to remove the resist from the wafer; and (7) chip  
inspection. Wafer processing is repeated as required (typically many times) to  
fabricate the desired semiconductor chips on the wafer.

20 FIG. 5 provides a flowchart of typical steps performed in microlithography, which is a principal step in wafer processing. The microlithography step typically includes: (1) resist-coating step, wherein a suitable resist is coated on the wafer substrate (which can include a circuit element formed in a previous wafer-processing step); (2) exposure step, to expose the resist with the desired pattern; (3)  
25 development step, to develop the exposed resist; and (4) optional annealing step, to stabilize or enhance the durability of the resist pattern.

Use of the alignment-mark-position detection method described above results  
in a microlithography process having improved accuracy, especially  
microlithography processes directed to achieving very fine linewidths. This is  
30 because methods according to the invention provide greater accuracy in alignment-  
mark detection. Greater detection accuracy is achieved especially whenever the

- 10 -

subject alignment mark is present on a substrate having pronounced crystalline properties, such as monocrystalline silicon, and the mark is being scanned with a beam having a relatively high energy level such as 100 keV.

Whereas the invention has been described in connection with a representative embodiment, it will be understood that the invention is not limited to that embodiment. On the contrary, the invention is intended to encompass all modifications, alternatives, and equivalents as may be included within the spirit and scope of the invention, as defined by the appended claims.

GPO:2024 OMB:2024

**What is claimed is:**

1. In a method for performing charged-particle-beam (CPB) microlithography of a specimen, a method for detecting a position of an alignment mark on the specimen, comprising:
  - (a) irradiating a charged particle beam onto an area of the specimen lacking an alignment mark, and detecting backscattered charged particles propagating from the irradiated area, so as to obtain a first backscattered-particle signal;
  - (b) irradiating the charged particle beam onto the alignment mark, and detecting backscattered charged particles propagating from the irradiated alignment mark, so as to obtain a second backscattered-particle signal;
  - (c) subtracting the first backscattered-particle signal from the second backscattered-particle signal to obtain a difference signal; and
  - (d) determining the alignment-mark position from the difference signal.
- 15 2. The method of claim 1, wherein step (a) is performed by scanning the charged particle beam across a smooth planar region of a surface of the specimen.
- 20 3. The method of claim 1, further comprising the steps of:  
storing data in the first backscattered-particle signal in a memory; and  
recalling the stored data from the memory and subtracting the recalled data from the second backscattered-particle signal to obtain the difference signal.
- 25 4. The method of claim 1, wherein:  
the specimen has a crystal-orientation plane;  
the first backscattered-particle signal is obtained by scanning the charged particle beam across a smooth planar region of a surface of the specimen representing a crystal-orientation plane of the specimen; and  
in step (c), the subtraction of the first backscattered-particle signal from the 30 second backscattered-particle signal removes data, concerning the crystal-orientation

of the substrate, from the difference signal that otherwise would obfuscate data in the difference signal pertaining to the alignment mark.

5. The method of claim 4, wherein:

5 the first backscattered-particle signal is further obtained by changing an angle of incidence of the charged particle beam as the beam is scanned across the smooth planar region of the surface; and  
a waveform of the first backscattered-particle signal exhibits a change in amplitude with corresponding changes in the angle of incidence.

10

6. In a charged-particle-beam (CPB) microlithography apparatus including a CPB source that produces a charged particle beam, a CPB-optical system through which the charged particle beam passes from the CPB source to a substrate, and a substrate stage on which the substrate is placed for exposure by the charged  
15 particle beam, a device for measuring an alignment of the substrate, the device comprising:

a deflector situated and configured to deflect the charged particle beam to cause the beam to irradiate a predetermined location on the substrate mounted on the substrate stage, so as to cause the location to produce backscattered particles;  
20 a backscattered-particle detector situated and configured to detect backscattered charged particles produced by the location on the substrate as the location is irradiated by the charged particle beam;  
a controller connected to the deflector and the backscattered-particle detector, the controller being configured to (i) energize the deflector in a manner causing the  
25 deflector to irradiate the beam on a first location on the substrate lacking an alignment mark, thereby producing a background backscattered-particle signal; (ii) energize the deflector in a manner causing the deflector to irradiate the beam on a second location on the substrate in which an alignment mark is formed, thereby producing an alignment-mark backscattered-particle signal; (iii) calculate a  
30 difference signal by subtracting the background signal from the alignment-mark

RECORDED MAIL

signal; and (iv) determine the position of the alignment mark from the difference signal.

7. A CPB microlithography apparatus, comprising a device for  
5 measuring substrate alignment as recited in claim 6.

8. A method for performing charged-particle-beam (CPB) microlithography of a specimen, comprising:

10 mounting the specimen on a substrate stage;  
detecting a position of an alignment mark on the specimen using a method as recited in claim 1; and  
microlithographically exposing a pattern onto the substrate.

9. A microelectronic-device fabrication process, comprising the steps:  
15 (a) preparing a wafer specimen;  
(b) processing the wafer specimen;  
(c) assembling devices formed on the wafer specimen during steps (a) and (b), wherein step (b) comprises a method for performing CPB microlithography as recited in claim 8.

20  
10. A microelectronic-device fabrication process, comprising the steps:  
(a) preparing a wafer substrate;  
(b) processing the wafer substrate;  
(c) assembling devices formed on the wafer substrate during steps (a) and  
25 (b), wherein step (b) comprises the steps of (i) applying a resist to the wafer substrate; (ii) microlithographically exposing the resist; and (iii) developing the resist; and step (ii) comprises providing a CPB microlithography apparatus as recited in claim 7; and using the CPB microlithography apparatus to expose the resist with a pattern.

11. A microelectronic device, produced using a method as recited in claim 10.

12. A microelectronic device, produced using a method as recited in  
5 claim 9.

**ALIGNMENT-MARK DETECTION METHODS AND DEVICES**  
**FOR CHARGED-PARTICLE-BEAM MICROLITHOGRAPHY,**  
**AND MICROELECTRONIC-DEVICE MANUFACTURING**  
**METHODS COMPRISING SAME**

5

**Abstract of the Disclosure**

Methods and devices are provided that achieve accurate detection of the positions of alignment marks on wafer substrates and other specimens as used in charged-particle-beam (CPB) microlithography. A charged particle beam (e.g., 10 electron beam) is irradiated onto an area, of a specimen, lacking an alignment mark to obtain a first backscattered-particle signal regarded as "background." The beam is irradiated onto an area, of the specimen, where an alignment mark is present to obtain a second backscattered-particle signal. The difference of the first signal from the second signal is determined to produce a difference signal containing data 15 concerning only aspects of the alignment mark and not of the background. The methods are especially useful whenever the specimen has crystalline properties that otherwise could affect the backscattered-particle signal.

合衆国法律集、第 35 編 § 120 に基づき、下記の合衆国出願の特許権を主張し、さらに当該出願の各請求項の内容が合衆国法律集、第 35 編 § 112、第 1 項に記載された方法で以前の合衆国出願で開示されていない限りにおいて、米国特許施行規則集 (37 CFR) § 1.56 での定義に基づき、先願日と当該出願についての国内出願日または PCT 国際出願日の間に発生した重要な情報を開示する義務を認める。

I hereby claim the benefit under Title 35, United States Code, § 120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, § 112, I acknowledge the duty to disclose material information as defined in Title 37, Code of Federal Regulations, § 1.56 which occurred between the filing date of the prior application and the national or PCT International filing date of this application:

(Application Serial No./ 出願番号)	(Filing Date/ 出願日)	(Status: Patented, Pending, Abandoned/ 状況: 特許取得、特許出願中、放棄)

--------------------------------	--------------------	--

ここでなされた当方の認識についての声明はすべて正確で、情報および信念に関してなされた声明は正確であると信じることをここに宣言する。さらに、故意の虚偽声明および類似の声明が合衆国法律集 (18 USC) § 1001 において罰金または拘禁、あるいはその両方によって罰せられ、またそのような故意の虚偽声明が開示または発行される特許の有効性を危うくする可能性があることを理解の上で、これらの声明を行ったことをここに宣言する。

委任状: 名前を挙げられた発明者として、当該出願を遂行し、さらに特許商標庁に關係する全業務を行うよう下記の弁護士や代理人をこれに指名する (名前と登録番号を一覧する)。

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

**POWER OF ATTORNEY:** As a named inventor, I hereby appoint the following attorney(s) and/or agent(s) to prosecute this application and to transact all business in the Patent and Trademark Office connected therewith (list name and registration number):
